Outline

Fair division: taxonomy of problems

Computation and communication

Communication Combinatorial spaces and compact representation

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Centralized mechanisms

Cardinal, additive preferences Cardinal, non-additive preferences Ordinal, separable preferences Ordinal, nonseparable preferences

Decentralized mechanisms

Fair division problem (informal)

- ▶ a set of *n* agents
- a set of resources to be allocated
- agents have preferences over resources
- the final allocation is subject to some feasibility constraints

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

... a final allocation is found somehow

Fair division problem (informal)

- ▶ a set of *n* agents
- a set of resources to be allocated
- agents have preferences over resources
- the final allocation is subject to some feasibility constraints
- ... a final allocation is found somehow

Without additional parameters being fixed it is difficult to give a more precise definition.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

1. Centralized versus decentralized

Finding the allocation requires the agents to express, in one way or another, their preferences.

► The process that consists in querying the agents about their preferences is called *preference elicitation*.

Centralized mechanism There is a central authority that elicits the agents' preferences, and then determines the output allocation.

Decentralized / distributed mechanism There is no central authority, and the agents themselves compute the allocation, revealing their preferences by certain specific (inter)actions.

Partially decentralized mechanism interaction protocol + central authority

2. Divisible versus indivisible resources

Divisible resources (homogeneous or heterogeneous) Indivisible resources or *items*

3. Ordinal versus cardinal preferences

(for centralized and semi-centralized mechanisms)
Cardinal preferences Agents specify *numerical values* with (sets of) resources
Ordinal preferences Agents are only required to *rank* (sets of) resources

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

4. One-to-one versus many-to-one

(for indivisible resources)

One-to-one allocation

Each agent gets exactly one item: *matching problem* Many-to-one allocation Each agent gets possibly several items.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

5. Deterministic versus randomized

Deterministic allocation Output = single allocation (possibly using some tie-breaking mechanism)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Randomized allocation Output = probability distribution over allocations.

6. Money or not

Money Agents may pay and/or receive money No money

7. Initial endowments or not

Initial endowments The agents initially own resources (other than money) No initial endowments

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Fair division

10. (...)

for (almost) all the rest of the lecture

Centralized fair division

(From now on: indivisible goods)

Given

- a set of *m items* to be allocated,
- a set of n agents,
- preferences of agents over items,
- ▶ the final allocation being subject to some feasibility constraints,

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

criteria for evaluating the quality of allocations

the central authority determines an allocation of items to agents

Decentralized fair division

Given

- a set of *m items* to be allocated
- a set of n agents
- the final allocation being subject to some feasibility constraints
- criteria for evaluating the quality of allocations,

an interaction protocol between the agents is performed, resulting in an allocation.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Semi-decentralized fair division

Given

- a set of *m items* to be allocated
- a set of n agents
- the final allocation being subject to some feasibility constraints
- criteria for evaluating the quality of allocations,

an interaction protocol between the agents and the central authority is performed, resulting in an allocation.

Decentralized mechanisms

Computation and communication

Computation What are the computational resources (time and space) needed to determine the outcome of the mechanism? How should this outcome be computed in practice?

- ► an algorithm A computes a mechanism F if for any instance I, running A on I outputs F(I).
- (very informally) cost of an algorithm: worst case number of resources, over all instances, used by the algorithm.
- computational complexity of mechanism: cost of the cheapest algorithm that computes it.

Computation and communication

İ

Communication What is the length of the interaction between the agents (and possibly the central authority) needed to determine the outcome of the mechanism? How should this interaction be performed?

- ▶ a *communication protocol* \mathcal{P} is similar to an algorithm, but the basic elements are communication acts instead of instructions for the computer.
- ▶ P is a protocol for a mechanism F if for any instance I, executing P on I outputs F(I).
- cost of a protocol: worst case number of bits, over all instances, exchanged between the agents between themselves and/or with the central authority.
- communication complexity of mechanism: cost of its cheapest protocol.

Communication: centralized mechanisms

A centralized protocol works as follows:

- 1. each agent reports her preferences P_i (ordinal or cardinal), in some format
- 2. the central authority computes $F(P_1, \ldots, P_n)$
- communication complexity of F = number of bits needed to specify P_1, \ldots, P_n
- D space of all admissible preferences (preference relations or utility functions)

- each agent needs to send at most $\log |D|$ bits
- communication complexity: $O(n \log |D|)$
- this upper bound is not always reached
- find some mechanisms needing less communication

Preferential dependencies

Existence of *preferential dependencies* between variables:

- I'd like to have two consecutive time slots for my lectures (but not three)
- if I don't get the shared custody of the children then at least I'd like to keep the cat
- I want Ann or Charles or Daphne in my team, each of whom would be an excellent goal keeper
- if I receive a left shoe then my value for a right shoe is higher than in the opposite case.

 - (can be completed so as to be) separable
 - not additively separable

$$\begin{array}{ll} (1) & af \succ cd \Rightarrow v(a) + v(f) > v(c) + v(d) \\ (2) & ce \succ bf \Rightarrow v(c) + v(e) > v(b) + v(f) \\ (3) & bd \succ ae \Rightarrow v(b) + v(d) > v(a) + v(e) \\ (2) + (3) & v(c) + v(d) > v(a) + v(f) \end{array}$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへ⊙

Preferences over bundles

- ► N set of agents
- $O = \{o_1, \ldots, o_m\}$ indivisible items

Notation: $[o_1o_2|o_3|o_4o_5]$ is the allocation where that agent 1 receives $\{o_1o_2\}$, 2 receives $\{o_3\}$, 3 receives $\{o_4, o_5\}$.

"No externality" assumption:

an agent's preferences bear only on the bundle she receives

- ▶ 1 is indifferent between $[o_1o_2|o_3|o_4o_5]$ and $[o_1o_2|o_3o_5|o_4]$
- ▶ 2 is indifferent between $[o_1o_2|o_3|o_4o_5]$ and $[\emptyset|o_3|o_1o_2o_4o_5]$
- etc.

Therefore: it is sufficient to know each agent's preferences over *bundles* (as opposed to her preferences over all allocations).

Preferences

Ordinal preferences

 $\succeq \text{ weak order on } \mathcal{X}$ $x \succeq y \qquad x \text{ is at least as good as } y$ $x \succ y \qquad \Leftrightarrow \qquad x \succeq y \text{ and not } y \succeq x \text{ (strict preference)}$ $x \sim y \qquad \Leftrightarrow \qquad x \succeq y \text{ and } y \succeq x \text{ (indifference)}$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Cardinal preferences

$$u:\mathcal{X}\to\mathbb{R}$$

Dichotomous preferences

 $A \subseteq \mathcal{X}$ set of acceptable bundles

Monotonicity

- $O = \{o_1, \ldots, o_m\}$ indivisible items
- 2⁰ set of all bundles of items
- $\mathcal{X} \subseteq 2^O$ set of admissible bundles that an agent may receive

Typically, preferences over bundles are *monotonic*: receiving one more item never makes an agent less happy. (*In particular: no bads, no chores*).

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

- ▶ ordinal preferences: if $S \supseteq S'$ then $S \succeq S'$
- ▶ cardinal preferences: if $S \supseteq S'$ then $u(S) \ge u(S')$

Strict monotonicity:

- ordinal preferences: if $S \supset S'$ then $S \succ S'$
- ▶ cardinal preferences: if $S \supset S'$ then u(S) > u(S')

- $O = \{o_1, \ldots, o_m\}$ indivisible items
- 2^O set of all bundles of items
- $\blacktriangleright \ \mathcal{X} \subseteq 2^{\mathcal{O}}$ set of admissible bundles that an agent may receive

Each agent has to express her preferences over \mathcal{X} :

Sometimes, this is not a problem (for instance: one-to-one allocation)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

• However, generally $\mathcal X$ has a heavy combinatorial structure

The combinatorial trap...

Two items... $o_1 o_2 \succ o_2 \succ o_1 \succ \varnothing \to 4$ subsets to compare

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

The combinatorial trap...

Four items... $o_1 o_2 o_3 o_4 \succ o_1 o_2 o_4 \succ o_1 o_3 o_4 \succ o_2 o_3 o_4 \succ o_1 o_2 o_3 \succ o_1 o_3 \succ o_2 o_4 \succ o_3 o_4 \succ o_1 o_4 \succ o_1 \sim o_2 \succ o_4 \succ o_3 \succ \varnothing \rightarrow 16$ subsets

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

The combinatorial trap...

Twenty items...

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

 \rightarrow 1048575 subsets \rightarrow the expression takes more than 12 days.

The dilemma

- ▶ The expression of *preferential dependencies* is often necessary.
- ▶ but... Eliciting and representing > or u in extenso is unfeasible in practice.

Centralized mechanisms

Cardinal, additive preferences Cardinal, non-additive preferences Ordinal, separable preferences Ordinal, nonseparable preferences

Decentralized mechanisms
Centralized mechanisms: cardinal, additive preferences

- each agent *i* specifies a value $u_i(o_j)$ for each $o_j \in O$.
- for each $S \subseteq O$, $U_i(S) = \sum_{o \in S} u_i(o)$.

Two possible approaches:

- $1. \ \mbox{fix}$ an optimization criterion and output the optimal allocation
- 2. fix a set of properties that we want the allocation to satisfy, and check if there is one.

Centralized mechanisms: cardinal, additive preferences

- each agent *i* specifies a value $u_i(o_j)$ for each $o_j \in O$.
- for each $S \subseteq O$, $U_i(S) = \sum_{o \in S} u_i(o)$.

Two possible approaches:

- 1. fix an optimization criterion and output the optimal allocation
- 2. fix a set of properties that we want the allocation to satisfy, and check if there is one.

Centralized, additive preferences: maximizing social welfare

utilitarian social welfare:

$$U(\pi) = \sum_{i=1}^n U_i(\pi(i))$$

egalitarian social welfare:

$$U(\pi) = \max_{i=1,\dots,n} U_i(\pi(i))$$

egalitarian social welfare, leximin refinement:

- if $U = (U_1, \ldots, U_n)$ then $U^{\uparrow} = (U_1^{\uparrow}, \ldots, U_n^{\uparrow}) = (U_{\sigma(1)}, \ldots, U_{\sigma(n)})$ where σ is a permutation of $\{1, \ldots, n\}$ such that $U_{\sigma(1)} \leq \ldots \leq U_{\sigma(n)}$.
- ► $(U_1, ..., U_n)$ leximin-dominates $(V_1, ..., V_n)$ if there exists a k such that $U_k^{\uparrow} > V_k^{\uparrow}$ and for each j < k, $U_j^{\uparrow} = V_j^{\uparrow}$.

Nash social welfare:

$$U(\pi) = \prod_{i=1}^n U_i(\pi(i))$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ ◆□ ◆ ◆○◆

Brief incursion into computational complexity

- search problem: given a relation F between instances and solutions: given instance I, output a solution s such that F(I, s), if such a solution exists.
- ▶ decision problem: given a set of instances I and a subset I⁺ of positive instances: given instance I, is it true that I ∈ I⁺?
- a decision or search problem is in class P (*deterministic polynomial time*) if it can be solved by an algorithm running in an amount of time bounded by a polynomial function of the size of the instance.
- (informally) a decision problem is in NP (*nondeterministic polynomial time*) if given a solution of the problem, this solution can be verified in deterministic polynomial time.
- (informally) a decision or search problem is NP-hard if it is "at least as difficult" as all problems in NP.
- ▶ a decision problem is NP-complete if it is (a) in NP and (b) NP-hard.
- ▶ is is strongly believed that P is strictly contained in NP.

Centralized, additive preferences, utilitarian social welfare

simply allocate each item to the agent who values it best

$$o_j \in \pi(i) ext{ if } o_j = rgmax_{o \in O} u_i(o)$$

- little to do with fairness, even if values are normalized
- obviously in P (but becomes NP-hard if preferences are not additively separable)

Centralized, additive, egalitarian: the Santa Claus problem

- centralized mechanism; cardinal, additive preferences;
- egalitarian social welfare

$$U(\pi) = \max_{i=1,\ldots,n} U_i(\pi(i))$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

return an allocation maximizing egalitarian social welfare.

The Santa Claus problem: computational complexity

- 1. Bad news: computing an optimal egalitarian allocation is NP-hard, even in the simple case of two agents with identical preferences.
- 2. Good news: the problem is *pseudo-polynomial* for a fixed number of agents.

- 3. (Rather) good news: polynomial approximation algorithms.
- 4. Good news: translation into integer linear programming.

The Santa Claus problem: NP-hardness

Bad news: NP-hardness, even for two agents with identical valuations.

- SUBSET SUM: given a collection of integers S = (s₁,..., s_p) and an integer K, is there a subset S' of S such that ∑_{i∈S'} s_i = K?
- ► (S = (3,3,5), K): positive instance of SUBSET SUM for K = 3,5,6,8,11
- ▶ PARTITION subproblem of SUBSET SUM where $\sum_{i=1}^{m} s_i = 2K$.
- PARTITION, and a fortiori SUBSET SUM, are known to be NP-complete
- ▶ reducing PARTITION to OPTIMAL EGALITARIAN ALLOCATION:

Good news: pseudo-polynomiality for a fixed number of agents

- $\blacktriangleright \text{ let } W = \max_{i,j} u_i(o_j)$
- there exists an algorithm that finds an optimal allocation in time O(W.2ⁿpol(n, m))
- does this mean that the problem is in P if the number of agents is a constant?

Good news: pseudo-polynomiality for a fixed number of agents

• let $W = \max_{i,j} u_i(o_j)$

- there exists an algorithm that finds an optimal allocation in time O(W.2ⁿpol(n, m))
- does this mean that the problem is in P if the number of agents is a constant? No, because the size needed to represent W is log W.
- ► O(W.2ⁿpol(n, m)) is polynomial in the size of the input if both W and n are (bounded by a) constant.
- informally: if the valuations are small, and the number of agents is small too, then computing an optimal egalitarian allocation is easy.

We will now find such an algorithm

- 1. first in the simple case n = 2 and identical valuations.
- 2. then n = 2, any valuations
- 3. then in the general case: n constant > 2.

1. $\mathbf{n} = 2$ and identical valuations

• Input
$$\alpha_1 = u_1(o_1) = u_2(o_1), \dots, \alpha_m = u_1(o_m) = u_2(o_m)$$

• $K = \left\lceil \left(\sum_{i=1}^m \alpha_i \right) / 2 \right\rceil$

- we construct a table T(w, i) for each w = 0, ..., K and i = 1, ..., m
- ► T(w, i) contains a subset of {α₁,..., α_i} of sum w if such a subset exists; otherwise, T(w, i) = nil.

$$T(\alpha_1, 1) \leftarrow \{o_1\}; T(0, 1) \leftarrow \emptyset; \text{ for } w \notin \{0, \alpha_1\}: T(w, 1) \leftarrow \textit{nil.}$$

for $i = 2, \ldots, m$

for
$$w = 0, ..., K$$

if $T(w, i - 1) \neq nil$
then $T(w, i) \leftarrow T(w, i - 1)$
else if $T(w - \alpha_i, i - 1) \neq nil$
then $T(w, i) \leftarrow T(w, i - 1) \cup \{o_i\}$
else $T(w, i) \leftarrow nil$ endif

end for

end for

$$w^* \leftarrow \max\{w, T(w, m) \neq nil\};$$

return the allocation $[T(w^*, m) \mid \overline{T(w^*, m)}]_{m}$

2. $\mathbf{n} = 2$ and any valuations

- Input: for each $i = 1, \ldots, m$: $\alpha_i = u_1(o_i), \beta_i = u_2(o_i)$
- $K = \left[\left(\sum_{i=1}^{m} \max(\alpha_i, \beta_i) \right) / 2 \right]$
- construct partial allocation π(v, w, i) for each (v, w) ∈ {0,...,K}² and each i ≤ m
- π(v, w, i) contains a partial allocation of {o₁,..., o_i} giving utility v
 to agent 1 and w to agent 2 if there is one; π(v, w, i) = nil otherwise

A D N A 目 N A E N A E N A B N A C N

2. $\mathbf{n} = 2$ and any valuations

$$\begin{split} \pi(0,0,1) \leftarrow [\varnothing|\varnothing];\\ \text{for each } (v,w) \neq (0,0): \ \pi(w,w,1) \leftarrow nil \ \text{end for}\\ \text{for } i=1,\ldots,m\\ \text{for } (v,w) \in \{0,\ldots,K\} \times \{0,\ldots,K\}\\ & \text{ if } \pi(v-\alpha_i,w,i-1) \neq nil\\ & \text{ then } \pi(v,w,i) \leftarrow \pi(v,w,i-1) + (o_i|\varnothing);\\ & \text{ else if } \pi(v,w-\beta_i,i-1) \neq nil\\ & \text{ then } \pi(v,w,i) \leftarrow \pi(v,w,i-1) + (\varnothing|o_i);\\ & \text{ else } \pi(w,i) \leftarrow nil \ \text{ endif} \end{split}$$

end for

end for

let (v^*, w^*) s.t. min (v^*, w^*) is maximal and $\pi(v^*, w^*, m) \neq nil$; return $\pi(v^*, w^*, m)$

- 3. general case: **n** constant + any valuations
- ► Input: for each i = 1, ..., n, j = 1, ..., m: $u_i^j = u_1(o_j)$. ► $K = \left\lceil \left(\sum_{j=1}^m \max(u_1^j, ..., u_n^j) \right) / n \right\rceil$
- ▶ construct $\pi(v, w, i)$ for all $(v_1, ..., v_n) \in \{0, ..., K\}^n$ and all $i \le m$
- ★ π(v, w, i) contains a partial allocation of {o₁,..., o_i} giving utility v_i to agent i if there is one; π(v, w, i) = nil otherwise
- time needed to fill the table $O(m.K^n)$
- remains polynomial in the size of the input if K and n are constant
- works more generally for any notion of social welfare defined by a polynomially computable aggregation function *

3. general case: \mathbf{n} constant + any valuations

- let $W = \max_{i,j} u_i(o_j)$
- there exists an algorithm that finds an optimal allocation in time O(W.2ⁿpol(n, m))
- ► the size needed to represent W is log W, therefore O(W.2ⁿpol(n, m)) is polynomial in the size of the input if W and n are constant.
- informally: if the valuations are small, and the number of agents is small too, computing an optimal egalitarian allocation is easy.

A D N A 目 N A E N A E N A B N A C N

The Santa Claus problem: polynomial approximation Good news, 2: *polynomial approximation*

• first for n = 2 and identical valuations $\alpha_1, \ldots, \alpha_m$

• Input
$$\alpha_1 = u(o_1), \ldots, \alpha_m = u(o_m)$$

• for each $S \subseteq \{1, \ldots, n\}$: $V(S) = \sum_{j \in S} \alpha_j$.

- ▶ Problem P(k): find S s.t. V(S) is maximal but no larger than k.
- a greedy approximation algorithm for P(k):

```
S \leftarrow \varnothing
for i = 1 to n
if \alpha_i + V(S) \le K
then S \leftarrow S \cup \{j\}
endif
end for
return S
```

- let S* be the optimal subset
- show that $V(S) \geq \frac{1}{2}V(S^*)$
- ▶ show that the $\frac{1}{2}$ bound is asymptoically reached.

• n = 2 and identical valuations $\alpha_1, \ldots, \alpha_m$

- ▶ S^* optimal subset: $V(S^*)$ maximal subject to $V(S^*) \le k$
- $\pi^* = [S^* \mid \overline{S^*}]$ optimal egalitarian solution
- $\pi = [S \mid \overline{S}]$ returned by the algorithm
- $\min_{i=1,2} u_i(\pi(i)) \leq \frac{1}{2} \min_{i=1,2} u_i(\pi^*(i))$
- the algorithm is a polynomial 2-approximation algorithm.

can we get a better polynomial approximation? yes

- n = 2 and identical valuations $\alpha_1, \ldots, \alpha_m$
- problem P: optimize egalitarian social welfare
- exact algorithm: at each step *i*, construct the list of all reachable sums from {α₁,..., α_i}: exponential time
- greedy algorithm: at each step, store exactly one number: linear time, approximation guarantee = 2
- inbetween: at each step, keep a list of reachable sums of "reasonable cardinality"
- ▶ given parameter δ, trim the current list of possible sums L into L' by removing elements as long as for every y ∈ L there exists z ∈ L' such that (1 − δ)y ≤ z ≤ y.

We want a polynomial *r*-approximation algorithm for each r > 1.

▶ input: without loss of generality, $\alpha_1 \ge \alpha_2 \ge \ldots \ge \alpha_m$

$$\delta = \frac{r-1}{m}$$

$$L_0 = \{0\}$$
for $j = 1$ to m **do**

$$L_i \leftarrow MergeLists(L_i, L_{i-1} + \alpha_i)$$

$$L_i \leftarrow Trim(L_i, \delta)$$
remove from L all elements bigger than K
return the partition corrresponding to the largest element from L_m

- ▶ the algorithm gives a *r*-approximation of the initial problem
- ► complexity: $O(m^2 \log(K)/1 r)$: polynomial in the size of the input data and in $\frac{1}{1-r}$
- ► A is a fully polynomial-time approximation scheme for problem P.

- 2 agents with identical valuations: fully polynomial-time approximation scheme
- it does not carry on to the general case:
 - approximated to a factor m n + 1
 - cannot be approximated to a factor < 2, unless P = NP (Bezakova and Deni, 2005)

The Santa Claus problem: translation into ILP

Good news, 3: translation into zero-one linear programming

- ▶ Input: *n* agents, *m* items, valuations $u_i^j = u_i(o_j)$
- Goal: find an allocation maximizing min_i $\sum_{j \in \pi(i)} v_i(o_j)$
- introduce *nm* variables x_i^j (agent *i* gets item o_j)
- solve the following problem:

$$\begin{aligned} \max(t) \\ s.t. & \left| \begin{array}{ll} \sum_{j=1}^{m} x_i^j u_1^j \geq t & \forall i = 1, \dots, n \\ \sum_{i=1}^{n} x_i^j = 1 & \forall j = 1, \dots, m \\ x_i^j \in \{0, 1\} & \forall i, j \end{array} \right. \end{aligned}$$

 zero-one linear programming is NP-hard but there exist now very good off-the-shelf solvers.

Centralized, additive preferences, leximin

• compute
$$w_1 = \max_{\pi} \min_i u_i(\pi(i))$$

• for $k = 1, \ldots, n$, solve P_k :

$$\max(t)$$

$$s.t. \begin{vmatrix} \sum_{j=1}^{n} x_{k}^{j} = w_{1} \\ \sum_{j=1}^{m} x_{1}^{j} u_{1}^{j} \ge t \quad \forall i \neq k \\ (...) \end{vmatrix}$$

- w_2 : maximal value obtained for P_1, \ldots, P_n .
- for $(k, k') = 1, \ldots, n, k \neq k'$, solve $P_{k,k'}$:

$$\max(t)$$

$$s.t. \begin{vmatrix} \sum_{j=1}^{n} x_{k}^{j} = w_{1} \\ \sum_{j=1}^{n} x_{k'}^{j} = w_{2} \\ \sum_{j=1}^{m} x_{1}^{j} u_{1}^{j} \ge t \quad \forall i \neq k, k' \\ (...) \end{vmatrix}$$

- w_3 : maximal value obtained for all $P_{k,k'}$.
- for all (k, k', k''), solve $P_{k,k',k''}$:
- etc.

Centralized, additive preferences, leximin

- exponential number of 0-1 linear programs
- but polynomial number of n is a constant
- other algorithms (Bouveret and Lemaître, 2009)

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Centralized, additive preferences, Nash

- maximize $U(\pi) = \prod_{i=1}^{n} U_i(\pi(i))$
- NP-hard
- pseudo-polynomial for constant number of agents
- constant factor approximation $2e^{1/e} \approx 2.9$ (Cole & Gkatzelis, 2017)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

solvable by a convex integer program

Centralized mechanisms: cardinal, additive preferences

Two possible approaches:

- $1. \ \mbox{fix}$ an optimization criterion and output the optimal allocation
- 2. fix a set of properties that we want the allocation to satisfy, and check if there is one.

- π is envy-free if for all $i, j, u_i(\pi(i)) \ge u_i(\pi(j))$
- envy-freeness has to be coupled with an efficiency criterion, in particular:
 - completeness: all items must be allocated
 - Pareto-efficiency: no allocation π' is at least as good as π for all agents and strictly better for at least one agent.

envy-freeness + completeness

$$\sum_{k=1}^{m} x_{i}^{k} u_{i}^{k} \geq \sum_{k=1}^{m} x_{j}^{k} u_{i}^{k} \quad \forall i, j = 1, \dots, n \\ \sum_{i=1}^{n} x_{1}^{j} = 1 \qquad \forall j = 1, \dots, m \\ x_{i}^{j} \in \{0, 1\} \qquad \forall i, j$$

$$\begin{array}{ll} \sum_{k=1}^{m} (x_{i}^{k} - x_{j}^{k}) u_{i}^{k} \geq 0 & \forall i, j = 1, \dots, n \\ \sum_{i=1}^{n} x_{1}^{j} = 1 & \forall j = 1, \dots, m \\ x_{i}^{j} \in \{0, 1\} & \forall i, j \end{array}$$

- existence of a complete EF allocation is NP-complete
- degree of envy of an allocation

$$e(\pi) = \max_{i,j} \max(0, u_i(\pi(j)) - u_i(\pi(i)))$$

- Lipton, Markakis, Mossel, Saberi, 2004):
 - Let $\alpha = \max_{i,o} u_i(o)$. There always exists an allocation π such that $e(\pi) \leq \alpha$, and such an allocation can be found in time $O(mn^3)$.
 - If the utilities are identical: [fully] polynomial-time approximation scheme [for n constant]

- envy-freeness + Pareto-efficiency
- verifying that an allocation is complete and envy-free: $O(n^2m)$
- ▶ therefore: existence of an envy-freene + complete allocation is in NP
- does this extend to the existence of an envy-free and Pareto-efficient allocation?

- checking whether an allocation is envy-free: polynomial.
- checking whether an allocation is Pareto-efficient:

envy-freeness + Pareto-efficiency

- verifying that an allocation is complete and envy-free: $O(n^2m)$
- ▶ therefore: existence of an envy-freene + complete allocation is in NP
- does this extend to the existence of an envy-free and Pareto-efficient allocation?
 - checking whether an allocation is envy-free: polynomial.
 - checking whether an allocation is Pareto-efficient: coNP-complete. A problem *I*, *I*⁺ is in coNP if its complement problem *I*, *I*⁻ is in NP.

- envy-freeness + Pareto-efficiency
- verifying that an allocation is complete and envy-free: $O(n^2m)$
- ▶ therefore: existence of an envy-freene + complete allocation is in NP
- does this extend to the existence of an envy-free and Pareto-efficient allocation?
 - checking whether an allocation is envy-free: polynomial.
 - checking whether an allocation is Pareto-efficient: coNP-complete.
 - existence of an envy-free and Pareto-efficient allocation: in Σ^p₂
 - Σ₂^p = NP^{NP} set of problems solvable by a nondeterministic polynomial algorithm equipped with NP-oracles.

- strongly believed that NP ≠ coNP and that both are strictly contained in ∑^p₂.
- de Keijzer, Bouveret, Klos and Zhang, 2009: Σ_2^p -complete.

Given a fair division problem:

for each agent *i*, the maximin fair share value of *i* is her value of the worst share of the best possible partition

$$MmFS(i) =: \max_{\pi} \min_{j} u_i(\pi(j))$$

• π satisfies the maxmin fair share property if for all *i*,

$$u_i(\pi(i)) \geq MmFS(i)$$

- weaker than envy-freeness
- under additive preferences, a maxmin fair share allocation always exists (a) for n = 2, and (b) for any n and identical preferences.
- in the general case, it is difficult to find a problem with no maxmin fair share allocation (Bouveret and Lemaitre 2014) but counterexamples exist (Procaccia and Wang 2014).

given i's preferences and the number of agents n, computing MmFS(i) is NP-hard, even with n = 2(reduction from PARTITION).

given problem P and allocation π, what is the complexity of determining whether π satisfies the maxmin fair share property?.

- ▶ given *i*'s preferences and the number of agents *n*, computing *MmFS(i)* is NP-hard, even with *n* = 2(reduction from PARTITION).
- given problem P and allocation π, what is the complexity of determining whether π satisfies the maxmin fair share property?.
 - ▶ in NP: for each i = 1, ..., nguess π^i check that $u_i(\pi(i) \ge u_i(\pi^i(j))$ for each j = 1, ..., mend for

- ► NP-hard: reduction from PARTITION.
- NP-complete.

- ▶ given *i*'s preferences and the number of agents *n*, computing *MmFS(i)* is NP-hard, even with *n* = 2(reduction from PARTITION).
- given problem P and allocation π, what is the complexity of determining whether π satisfies the maxmin fair share property? NP-complete.
- given problem P, compute a maxmin fair share allocation: NP-hard, even for two agents with identical preferences.

given problem P, determine if there exists a maxmin fair share allocation:

```
    in NP:
guess n + 1 allocations π, π<sup>1</sup>,..., π<sup>n</sup>
check that u<sub>i</sub>(π(i) ≥ u<sub>i</sub>(π<sup>i</sup>(j)) for each j = 1,..., m
    NP-hard?
```
Centralized, additive preferences, proportional and minmax fair share

Given a fair division problem:

- ▶ the proportional fair share value of *i* is $PFS(i) = \frac{1}{n} \sum_{i=1}^{m} u_i^j$
- π satisfies the proportional fair share property if for all i,
 u_i(π(i)) ≥ PFS(i)
- the minmax fair share value of i is her value of the best share of the worst possible partition:

$$mMFS(i) = \min_{\pi} \max_{j} u_i(\pi(j))$$

• π satisfies the minmax fair share property if for all *i*, $u_i(\pi(i)) \ge mMFS(i)$

- envy-freeness \Rightarrow minmax FS \Rightarrow proportional FS \Rightarrow FS
- complexity of verification, search and existence for proportional and minmax FS?

- Marine wants a beer.
- Jean-Luc wants a beer or a coffee.

How can we express such preferences in a succinct way?

Let *PS* be a set of *propositional symbols*. The propositional language generated from *PS* is the set of *formulas* L_{PS} defined as follows:

- every propositional symbol is a formula;
- \top and \bot are formulas;
- if φ is a formula then $\neg \varphi$ is a formula;
- ▶ if φ and ψ are formulas then $\varphi \land \psi$, $\varphi \lor \psi$, $\varphi \to \psi$, and $\varphi \leftrightarrow \psi$ are formula;

- op (true) and op (false): logical constants
- \neg (not): unary connective
- \wedge (and), \vee (or), \rightarrow (implies), \leftrightarrow (equivalent) : binary connectives.

An *interpretation* (or *valuation*) is a mapping from *PS* to $\{0,1\}$. An interpretation *I* is extended to formulas by the following rules:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

 $I(\top) = 1;$ $I(\bot) = 0;$ $I(\neg \varphi) = 1 - I(\varphi);$ $I(\varphi \lor \psi) = \max(I(\varphi), I(\psi));$ $I(\varphi \land \psi) = \min(I(\varphi), I(\psi));$ $I(\varphi \rightarrow \psi) = I(\neg \varphi \lor \psi);$ $I(\varphi \leftrightarrow \psi) = I((\varphi \rightarrow \psi) \land (\psi \rightarrow \varphi)).$ $I \text{ is a model of } \varphi, \text{ denoted } I \vDash \varphi, \text{ iff } I(\varphi) = 1$

 $Mod(\varphi) = \{I \mid I \vDash \varphi\}$

Validity φ is valid if $I(\varphi) = 1$ for every interpretation I $\models \varphi$ Satisfiability φ is satisfiable if $I(\varphi) = 1$ for at least one interpretation ILogical consequence ψ is a *logical consequence* of φ if every model of φ is a model of ψ $\varphi \models \psi$ Logical equivalence φ and ψ are *equivalent* if they are logical consequences of each other

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

 $\varphi\equiv\psi$

Some classes of formulas:

literals: atomic formulas or negations of atomic formulas

a ¬*b* ...

• clauses: disjunctions of literals, including \perp

 $a \lor \neg b \lor c$ $d \lor \neg d$ \bot ...

- k-clauses: disjunctions of at most k literals
- cubes: conjunctions of literals, including the empty cube \top

 $a \wedge \neg b \wedge c$ $d \wedge \neg d$ \top ...

- k-clauses: conjunctions of at most k literals
- \blacktriangleright *positive formulas*: formulas in which the only connectives appearing are \land and \lor

$$a \wedge (b \vee c)$$
 $a \vee (b \wedge c)$...

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Binary variables

Particular case: binary variables $\rightarrow D_i = \{\top, \bot\}$ for all *i*. Can be used to represent subsets of elements.

Binary variables

Particular case: binary variables $\rightarrow D_i = \{\top, \bot\}$ for all *i*. Can be used to represent subsets of elements.

A set of elements $\mathcal{O} = \{o_1, \ldots, o_m\} \rightarrow \text{binary variables } \{o_1, \ldots, o_m\}$, where each variable O_i stands for the presence or absence of o_i .

 \rightarrow each instantiation / interpretation represents a subset π of ${\cal O}$

Example of application: allocation of indivisible items

Example: $o_1 \bar{o_2} \bar{o_3} o_4 \bar{o_5}$ represents the subset $\{o_1, o_4\}$.

Of logic and goals

Logic-based languages suit well when we have to deal with *binary variables* (*e.g.* resource allocation problems).

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- ► A propositional syntax *L*_O...
 - ▶ set of propositional symbols *O*,
 - usual connectives

Of logic and goals

Logic-based languages suit well when we have to deal with *binary variables* (*e.g.* resource allocation problems).

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

- ► A propositional syntax *L*_O...
 - ▶ set of propositional symbols *O*,
 - usual connectives

Example

Set of requests for one agent:

$$\cdot \bigcirc \land ((\blacksquare \land \heartsuit) \lor \blacksquare), \\ \cdot \bigtriangledown \land \diamondsuit.$$

What to do with all these goals ?

What to do with all these goals ?

A first (simplistic) example: dichotomous preferences. Example Variables $\mathcal{O} = \{o_1, o_2, o_3\}$

 $o_2 \land (o_1 \lor o_3)$

represents the dichotomous preference relation

 $\{o_1,o_2,o_3\}\sim\{o_1,o_2\}\sim\{o_2,o_3\}\succ \text{ all others subsets}$

- ▶ three items: one cup of coffee, one glass of beer, one sugar cube
- three agents: E(mmanuel), M(arine), J(ean-Luc), with dichotomous preferences:
 - Emmanuel wants a beer, or else coffee with sugar.
 - Marine wants a beer.
 - Jean-Luc wants a beer or a coffee.
- can they all be satisfied?
 - ▶ $b_J \lor c_J$ where b_J means: the beer is allocated to Jean-Luc
 - $b_E \vee (c_E \wedge s_E)$
 - ► b_M
 - ▶ constraints: $b_E \rightarrow \neg b_M \land \neg b_J$; etc. (an item is given to at most one agent)
 - (and possibly): $b_E \vee b_M \vee b_J$ etc. (every item must be allocated)
- allocations satisfying a maximum number of agents: model-preserving translation to MAXSAT

 $\begin{matrix} [c|-|b] & [c|b|-] & + \ s \ \text{to anybody} \ \text{(or to nobody, if allowed)} \\ [-|cs|b] & [b|cs|-] \end{matrix}$

Dichotomous preferences for fair division

- $\mathcal{X} = \{o_1, \ldots, o_m\}$ set of items
- $A \subseteq \mathcal{X}$ set of acceptable bundles
- agent i partitions the set of bundles A into two sets: acceptable and unacceptable bundles
- ▶ $b_E \lor (c_E \land s_E)$: Emmanuel is happy with $\{b\}$, $\{c, s\}$, $\{b, s\}$, $\{b, c\}$ and $\{b, c, s\}$, and unhappy with $\{c\}$, $\{s\}$ and \varnothing
- \blacktriangleright each set of acceptable bundles A is representable by a propositional formula φ_{E}
- ► a set of acceptable bundles A is monotonic if for all X ⊆ Y, X ∈ A implies Y ∈ A
- Remark A is monotonic iff φ_E is a positive formula (can be written with only ∧, ∨, but with no ¬)
 - $b \wedge \neg c$ (agent allergic to the smell of coffee): nonmonotonic

- Emmanuel wants a beer, or else coffee with sugar: $b_E \lor (c_E \land s_E)$
- Marine wants a beer: b_M
- Jean-Luc wants a beer or a coffee: $b_J \vee c_J$

An allocation π is *envy-free* if every agent is at least happy with her share than with any other agent's share

- $\pi_1 = [b| |c]$: Marine is envious of Emmanuel.
- ▶ $\pi_2 = [cs|b|-]$: Jean-Luc is envious of both Emmanuel and Marine.
- π₃ = [−| − |c]: envy-free, but not *Pareto-efficient*:
 [b| − |c] does at least as well as π₃ for all agents and strictly better
 for one (Emmanuel).

Here: no allocation is both envy-free and Pareto-efficient

Preferences slightly change: Emmanuel does not like beer anymore.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- Emmanuel wants a coffee with sugar: $c_E \wedge s_E$
- Marine wants a beer: b_M
- Jean-Luc wants a beer or a coffee: $b_J \vee c_J$
- [-|b|c] and [s|b|c]: envy-free and Pareto-efficient

- Emmanuel wants a coffee with sugar: $c_E \wedge s_E$
- Marine wants a beer: b_M
- Jean-Luc wants a beer or a coffee: $b_J \vee c_J$
- ► *EF*:

$$\begin{array}{ll} (b_J \lor c_J) \lor (\neg (b_E \lor c_E) \land \neg (b_M \lor c_M)) & \text{Jean-Luc not envious} \\ \land & (c_E \land s_E) \lor (\neg (c_M \land s_M) \land \neg (c_J \land s_J)) & \text{Emmanuel not envious} \\ \land & b_M \lor (\neg b_E \land \neg b_J) & \text{Marine not envious} \end{array}$$

 \blacktriangleright Γ : an item should not be given to more than one person

$$c_E \rightarrow (\neg c_M \land \neg c_J) \land \ldots$$

Pareto-efficiency: satisfy a maximal subset of

$$\Delta = \{b_J \lor c_J, c_E \land s_E, b_M\}$$

- EF-PE allocation \leftrightarrow maximal subset of Δ consistent with *EF* \wedge Γ
- model-preserving translation into default logic.
- practical computation: use efficient off-the shelf Answer Set Programming solvers

- EXISTENCE OF AN EFFICIENT, ENVY-FREE ALLOCATION is Σ_2^P -complete.
- complexity can fall down if
 - the number of agents is fixed to a small number, especially 2.
 - the agents are assumed to have identical preferences.
 - the agents' goals are restricted to a specific subclass of formulas.
 - Pareto-efficiency is replaced by the weaker completeness condition

- EXISTENCE OF AN EFFICIENT, ENVY-FREE ALLOCATION is Σ_2^P -complete.
- complexity can fall down if
 - the number of agents is fixed to a small number, especially 2.
 - the agents are assumed to have identical preferences.
 - the agents' goal are restricted to a specific subclass of formulas.
 - Pareto-efficiency is replaced by the weaker completeness condition

Retsircting the agents' goal to a specific subclass of formulas.

- ► if agents' preferences are represented by *cubes* then EXISTENCE OF AN EFFICIENT, ENVY-FREE ALLOCATION is NP-complete.
- ▶ if agents' preferences are represented by *clauses* then EXISTENCE OF AN EFFICIENT, ENVY-FREE ALLOCATION under this restriction is in P.

Representation language : $\langle L, I_L \rangle$, where

- L language
- ▶ $I_L : \Phi \in L \mapsto$ preference relation \succeq_{Φ} or utility function u_{Φ} induced by Φ

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Example 1: a language for dichotomous preferences:

L_{prop}: set of all propositional formulas built from the propositional symbols {*o*₁,..., *o_n*}

• $\varphi \in L \mapsto u_{\Phi}$ defined by u(S) = 1 if $S \vDash \varphi$, = 0 otherwise.

Example 1: a language for dichotomous preferences:

L_{prop}: set of all propositional formulas built from the propositional symbols {*o*₁,..., *o_n*}

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

• $\varphi \in L \mapsto u_{\Phi}$ defined by u(S) = 1 if $S \vDash \varphi$, = 0 otherwise.

Example

 $\mathcal{O} = \{ \mathbf{a}, \mathbf{b}, \mathbf{b}, \mathbf{b}, \mathbf{b}, \mathbf{b}, \mathbf{c},

Representation language : $\langle L, I_L \rangle$, where

- L language
- ▶ $I_L : \Phi \in L \mapsto$ preference relation \succeq_{Φ} or utility function u_{Φ} induced by Φ

Example 2: (obvious) language for additive utility functions:

L_{add}: set of all collections of real numbers

$$W = \{u_i, 1 \leq i \leq m\}$$
 for all $S \subseteq O$, $u_W(S) = \sum_{i, o_i \in S} u_i$

- Succinctness: (informally) language L₁ is at least as succinct as language L₂ is any preference structure expressible in L₂ can be expressed in L₁ without any exponential growth of size.
- Computational complexity: how hard is it to compare two alternatives or to find an optimal alternative when the preferences are represented in L?

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

On which criteria can we evaluate the different languages?

- Expressive power: what is the set of all preference structures expressible in the language?
- Succinctness: (informally) language L₁ is at least as succinct as language L₂ is any preference structure expressible in L₂ can be expressed in L₁ without any exponential growth of size.
- Computational complexity: how hard is it to compare two alternatives or to find an optimal alternative when the preferences are represented in L?

Easiness of elicitation

Preference elicitation = interaction with a user, so as to acquire her preferences, encoded in a language L.

Is it easy to construct protocols for eliciting the agent's preferences in *L*?

Compact representation languages: expressive power

Representation language: $\langle L, I_L \rangle$

Expressive power of a language = set of all preference structures that can be expressed in the language = $I_L(L)$.

 $\langle L, I_L \rangle$ at least as expressive as $\langle L', I_{L'} \rangle$ iff $I_L(L) \supseteq I_{L'}(L')$.

Examples :

- expressive power of L_{add} : all additive utility functions over \mathcal{X} ;
- expressive power of L_{exp} : all utility functions over \mathcal{X} .

 L_{exp} is more expressive than L_{add} .

Compact representation languages: succinctness

Relative notion:

 L_1 is at least as succinct as L_2 if there exists $F : L_2 \rightarrow L_1$ and a polynomial function p such that for all $\Phi \in L_2$:

- ► $I_{L2}(\Phi) = I_{L1}(F(\Phi))$: Φ and $F(\Phi)$ induce the same preferences
- $|F(\Phi)| \le p(|\Phi|)$: the translation is succinct

Example:

L_{exp,add} = explicit representation restricted to additive utility functions = set of all collections of pairs

$$U = \{ \langle x, u(x) \rangle | x \in \mathcal{X} \}$$

such that u is additively decomposable

► *L_{add}* is strictly more succinct than *L_{exp,add}*;

▶ but L_{exp} and L_{add} are incomparable because L_{exp} is more expressive than L_{add}.

Compact representation languages: computational complexity

What is the computational complexity of the following problems when the preferences on \mathcal{X} are represented in the language L:

Given an input Φ in the language L, ...

- ▶ DOMINANCE: and $x, y \in X$, do we have $x \succeq_{\Phi} y$?
- OPTIMISATION: find the preferred alternative (or one of the preferred alternatives)

(trivial for monotonic preferences)

► CONSTRAINED OPTIMISATION: and a subset C, possibly defined succinctly, find the preferred option (or one of the preferred options) x ∈ C.

Measuring hardness uses computational complexity notions.

k-additive utilities

A utility function over X = 2^O is k-additive if it can be expressed as the sum of sub-utilities over subsets of objects of cardinality ≤ k.

•
$$\Phi$$
: $u: \{S \subseteq O, |S| \le k\} \to \mathbb{R}$

$$u(x) = \sum_{S \subseteq O, |S| \le k} u(S)$$

Example: $O = \{a, b, c, d\}, k = 2$

u(a,b,d) = u(ab) + u(ad) + u(bd) + u(a) + u(b) + u(d)

k-additive utilities

- u is 1-additive $\Leftrightarrow u$ is additive
- every utility function is *m*-additive (m = |O|)
- a k-additive function can be also expressed as the sum of sub-utilities over subsets of attributes of cardinality exactly k.

$$u(x) = \sum_{S \subseteq O, |S|=k} v(S)$$

- can be specified by values v(S) for all |S| = k: $\begin{pmatrix} m \\ k \end{pmatrix}$ values
- polynomially large if k is a constant, otherwise exponentially large

k-additive utilities

An example

- O consists of 10 pairs of shoes
- ► u(S) = 10p + s if S contains a total of p matching pairs and in addition s single shoes
- u is 2-additive:
 - $u({left_i}) = u({right_i}) = 1$ for all i
 - $u(\{left_i, right_i\}) = 8$ for all i
- Exercise: express u as the sum of local values of sets of exactly two shoes.

k-additive utilities

Another example

Categorized domain: three attributes $N = \{main, dessert, wine\}$, and

 $\mathcal{X} = \{Meat, Fish, Veggie\} \times \{Apple, Cake\} \times \{Red, White\}$

 $u(vrc) = u_M(v) + u_D(c) + u_W(r) + u_{MW}(vr) + u_{MD}(vc) + u_{WD}(rc)$ = 12 + 5 + 0 + 0 + 3 + 0 = 18

Exercise: find the optimal alternative

k-additive form: complexity

For any $k \geq 2$:

given a k-additive representation...

- and an alternative x, computing u(x) is in P
- and a number α, checking that there exists an alternative x such that u(x) ≥ α is NP-complete
- ▶ finding x with u(x) maximal is NP-hard (except of course if we know beforehand that preference are monotonic...)

Generalized Additive Independence

GAI-decomposability

Let $\mathcal{X}_1, \ldots, \mathcal{X}_k$ be a family of subsets of N such that $\bigcup_i \mathcal{X}_i = N$. *u* is GAI-decomposable with respect to $\mathcal{X}_1, \ldots, \mathcal{X}_k$ if there exist *k* subutility functions

$$u_i: \mathcal{X}_i \to \mathbb{R}$$

such that

$$u(x) = \sum_{i=1}^{k} u_i(x_{\mathcal{X}_i})$$

• *k*-additivity = GAI-decomposability, with $|X_i| \le k$ for all *i*.

Generalized Additive Independence

 $N = \{$ first, main, dessert, wine $\}$

 $X = \{Soup, Pasta\} \times \{Meat, Fish, Veggie\} \times \{Apple, Cake\} \times \{Red, White\}$

 $\mathcal{X}_1, \dots, \mathcal{X}_k = \{\{\text{first}\}, \{\text{main}, \text{wine}\}, \{\text{main}, \text{dessert}\}\}$

U _{first}		U _{main,wine}			U _{ma}	U _{main,dessert}		
	I		r	W		а	С	
s p	2	т	13	7	m	2	0	
	3	f	9	15	f	0	0	
	L I	v	12	12	V	0	3	

- DOMINANCE is in P
- OPTIMISATION is NP-hard in the general case

Language L_W :

- G = a set of pairs $\langle \varphi_i, w_i \rangle$ where
 - φ_i is a propositional formula;
 - w_i is a real number

•
$$I_L(G) = u_G$$
 defined by: for all $x \in 2^{PS}$,

$$u_G(x) = \bigoplus \{ w_i \mid \langle \varphi_i, w_i \rangle \in G \text{ and } x \vDash \varphi \}$$

- \blacktriangleright \oplus non-decreasing, symmetric function
- two usual choices: $\oplus = +$ and $\oplus = \max$.
- rest of the talk: $\oplus = +$

Example

Computation of individual utility ($\oplus = +$) :

Example

Computation of individual utility ($\oplus=+)$:

$$\pi_1 = \{ \bigcirc, \blacksquare, \blacksquare, \boxtimes, \bigotimes \} \Rightarrow u_1(\pi_1) = \underbrace{ (\blacksquare \land \heartsuit) \lor \blacksquare }_{110}$$

Example

Computation of individual utility ($\oplus = +$) :

$$\pi_1 = \{ \bigcirc, \blacksquare, \blacksquare, \blacksquare, \diamondsuit \} \Rightarrow u_1(\pi_1) = 110 \bigcirc$$

Example

Computation of individual utility ($\oplus = +$) :

$$\pi_1 = \{ \bigcirc, \blacksquare, \blacksquare, \bowtie, \bigotimes \} \Rightarrow u_1(\pi_1) = 110 - 10 + 0$$

・ロト ・ 戸 ・ ・ ヨ ・ ・ ヨ ・ ・ つ へ ()

Example

Computation of individual utility ($\oplus = +$) :

$$\pi_1 = \{ \bigcirc, \blacksquare, \blacksquare, \bigtriangledown, \diamondsuit, \Rightarrow u_1(\pi_1) = 110 - 10 + 0 = 100 \}$$

Weighted logics: expressive power

Depends on the formulas and the weights allowed in the pairs $\langle \varphi, w \rangle$.

- positive cubes + all weights: fully expressive
- literals + all weights: additive functions
- 2-cubes + all weights: 2-additive functions
- cubes + positive weights: non-negative functions
- clauses + positive weights: a proper subset of all nonnegative functions

Hint $u({o_1, o_2}) = 1$, $u({o_1}) = u({o_2}) = 0$: not expressible!

- positive formulas + positive weights: monotonic non-negative functions
- positive cubes + positive weights: a proper subset of all monotonic non-negative functions

Weighted logics: succinctness

▶ all formulas + all weights: fully expressive

positive cubes + all weights: fully expressive

But

all formulas + all weights more succinct than positive cubes + all weights

Hint: try to express *u* defined by

$$u(x) = \max_{i=1,\dots,n} x_i$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Weighted logics: computational complexity

- comparing two alternatives: can be solved in polynomial time
- finding an optimal alternative: NP-complete in the general case, even for dichotomous utilities
- finding an optimal alternative: polynomial for some restrictions of the language

- monotonic fragment (no negation, positive weights)
- additive fragment (literals only)

Fair division: taxonomy of problems

Computation and communication

Communication Combinatorial spaces and compact representation

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Centralized mechanisms

Cardinal, additive preferences Cardinal, non-additive preferences Ordinal, separable preferences Ordinal, nonseparable preferences

Decentralized mechanisms

Centralized mechanisms, ordinal preferences

- each agent *i* has a private preference relation \succ_i over 2^O .
- the usual communication dilemma:
 - 1. either *i* specifies \succ_i in extenso: exponential communication cost.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

2. or domain restriction, the most common being *separability*.

Centralized mechanisms: ordinal, separable preferences

- each agent *i* reports a preference relation \triangleright_i over *O*
- \triangleright \triangleright_i is extended to 2^O :
- ≻_i is the monotonic and separable extension of ▷ to 2⁰, that is, the smallest preference relation ≻ over 2⁰ such that

- ▶ ≻ extends ▷: for all $o_i, o_j \in O$, $o_i \triangleright o_j$ implies $\{o_i\} \succ \{o_j\}$
- ► is separable
- ► is monotonic
- ▶ > sometimes called the *responsive extension* of \triangleright .

Monotonic separable extension

$$m = 2, o_1 \triangleright o_2$$

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

Monotonic separable extension

m = 3, $o_1 \triangleright o_2 \triangleright o_3$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Monotonic separable extension

m = 4, $o_1 \vartriangleright o_2 \vartriangleright o_3 \vartriangleright o_4$

▲ロト▲御ト▲臣ト▲臣ト 臣 めんぐ

Centralized mechanisms: ordinal, separable preferences

Pros:

• communication complexity: $O(m, \log m)$.

Cons:

assumes separability: what will an agent report if she prefers o₂ over o₃ when she has o₁ and o₃ over o₂ if not?

$$o_1o_2o_3 \succ o_1o_2 \succ o_2o_3 \succ o_1 \succ o_3 \succ o_2 \succ \varnothing$$

 $o_1 \rhd o_3 \rhd o_2$ or $o_1 \rhd o_2 \rhd o_3$?

produces a (very) partial order

Modal notions of efficiency and fairness

- $P = \langle \rhd_1, \ldots, \rhd_n \rangle$ where each \rhd_i is a ranking over O.
- ▶ $P^* = \langle \succ_1, \ldots, \succ_n \rangle$ where each \succ_i is the monotonic separable extension of \triangleright_i .
- completion of P*:

$$T = \langle T_1, \ldots, T_n \rangle$$

where each T_i is a linear order extending \succ_i .

For a fairness or efficiency concept Γ:

Possible Γ an allocation π is *possibly* Γ if there exists a completion T of P^* such that π satisfies Γ under T. Necessary Γ an allocation π is *necessarily* Γ if for every completion T of P^* , π satisfies Γ under T.

◆□▶ ◆□▶ ◆∃▶ ◆∃▶ = のへぐ

Modal notions of efficiency and fairness

- ► $P = (\triangleright_1, ..., \triangleright_n)$ $\mapsto R = (\succ_1, ..., \succ_n)$ collection of partial orders on 2⁰
- π possibly envy-free
 if it is envy-free for some complete extension of R
- π necessarily envy-free
 if it is envy-free for all complete extensions of R
- possible Pareto efficiency, necessary Pareto efficiency, etc: defined similarly.

Ranking single items

Simple characterization:

- π is necessarily envy-free if for all agents *i*, *j*, and all *k* ≤ |π_i|, *i* prefers his *k*th best item in π_i to the *k*th best item in π_i
- π is possibly envy-free if for all i, j, either |π_i| > |π_j| or for some
 k ≤ |π_i|, i prefers his kth best item in π_i to the kth best item in π_j.

 $\begin{array}{ll} \triangleright_1: & \mathbf{a} \triangleright b \triangleright c \triangleright d \triangleright e \triangleright f \\ \triangleright_2: & \mathbf{a} \triangleright d \triangleright b \triangleright c \triangleright e \triangleright f \\ \triangleright_3: & \mathbf{b} \triangleright a \triangleright c \triangleright d \triangleright f \triangleright e \\ \triangleright_4: & \mathbf{b} \triangleright a \triangleright \mathbf{c} \triangleright \mathbf{e} \triangleright f \triangleright d \end{array}$

possibly efficient, possibly envy-free not necessarily envy-free not necessarily efficient

Ranking single items

Simple characterization:

- π is necessarily envy-free if for all agents i, j, and all k ≤ |π_i|, i
 prefers his kth best item in π_i to the kth best item in π_j
- ★ π is possibly envy-free if for all i, j, either |π_i| > |π_j| or for some k ≤ |π_i|, i prefers his kth best item in π_i to the kth best item in π_i.

 $\begin{array}{ll} \triangleright_1: & a \triangleright b \triangleright c \triangleright d \triangleright e \\ \triangleright_2: & a \triangleright d \triangleright b \triangleright c \triangleright e \\ \triangleright_3: & b \triangleright a \triangleright c \triangleright d \triangleright e \\ \triangleright_4: & b \triangleright a \triangleright c \triangleright e \triangleright d \end{array}$

- is there a complete, possibly envy-free (PEF) allocation?
- if some agent receives nothing, she necessarily envies all those receiving something
- $\mathsf{PEF} \Rightarrow$ agent receives two items, three agents receive one item
- ▶ if 1 or 2 receive only one item, one of them will not get a and will necessarily envy someone; similarly for 3 and 4.
- ▶ if k distinct items are top-ranked by some agent, there exists a complete possibly envy-free allocation if and only if m ≥ 2n − k.
 [Remains true if complete is replaced by possibly Pareto-efficient.]

Ranking single items

Simple characterization:

- π is necessarily envy-free if for all agents *i*, *j*, and all *k* ≤ |π_i|, *i* prefers his *k*th best item in π_i to the *k*th best item in π_i
- ★ π is possibly envy-free if for all i, j, either |π_i| > |π_j| or for some k ≤ |π_i|, i prefers his kth best item in π_i to the kth best item in π_j.

1 and 4 leave:

 $\triangleright_2: \quad \mathbf{a} \triangleright \mathbf{d} \triangleright \mathbf{b} \triangleright \mathbf{c} \triangleright \mathbf{e} \triangleright \mathbf{f} \\ \triangleright_3: \quad \mathbf{b} \triangleright \mathbf{a} \triangleright \mathbf{c} \triangleright \mathbf{d} \triangleright \mathbf{f} \triangleright \mathbf{e}$

necessarily envy-free not necessarily efficient

Modal notions of efficiency and fairness

The following problems are NP-complete:

- existence of a complete necessarily envy-free allocation.
- existence of a possibly Pareto-optimal, necessarily envy-free allocation.
- existence of a necessarily Pareto-optimal, necessarily envy-free allocation.

Particular case of two agents (n = 2):

- \blacktriangleright a complete allocation π is necessarily envy-free if and only if
 - m is even
 - ▶ for i = 1, 2 and every $k = 1, ..., \frac{m}{2}$, π gives agent *i* at least *k* of her 2k 1 most preferred items.

 a complete allocation necessarily envy-free, if there exists ine, can be computed in polynomial time.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Centralized mechanisms

Cardinal, additive preferences Cardinal, non-additive preferences Ordinal, separable preferences Ordinal, nonseparable preferences

Decentralized mechanisms

Centralized mechanisms: ordinal, nonseparable preferences

 \blacktriangleright How can we express succinctly ordinal, nonseparable preferences over 2^{O}

- > a first possibility: conditionally lexicographic preferences
- > a second possibility: conditional importance networks

allow to express conditional importance statements such as

 $a\overline{b}$: $cde \triangleright fg$

 $\begin{array}{l} \mbox{if I have a and I do not have b} \\ \mbox{then I prefer to have $\{c,d,e\}$ rather than $\{f,g\}$} \\ \mbox{all other things being equal} \end{array}$

Conditional importance statement

 $\mathcal{S}^+, \mathcal{S}^- : \mathcal{S}_1 \triangleright \mathcal{S}_2$ (with \mathcal{S}^+ , \mathcal{S}^- , \mathcal{S}_1 and \mathcal{S}_2 pairwise-disjoint).

 \succ is compatible with $\mathcal{S}^+, \mathcal{S}^- : \mathcal{S}_1 \triangleright \mathcal{S}_2$ if for every $A, B \subseteq O$ such that

• $B \supseteq S_2$ and $A \not\supseteq S_2$

• for each $o \in O \setminus (S^+ \cup S^- \cup S_1 \cup S_2)$, we have $o \in A$ iff $o \in B$ then $A \succ B$

Example: $a\overline{d}$: $b \triangleright ce$ implies for example $ab \succ ace$, $abfg \succ acefg$, ... Cl-net

A CI-net on \mathcal{V} is a set \mathcal{N} of conditional importance statements on \mathcal{V} .

Conditional importance statement

 $S^+, S^- : S_1 \triangleright S_2$ (with S^+ , S^- , S_1 and S_2 pairwise-disjoint).

CI-net

A CI-net on $\mathcal V$ is a set $\mathcal N$ of conditional importance statements on $\mathcal V.$

Preference relation induced from a CI-net

 $\succ_{\mathcal{N}}$ is the smallest preference relation over 2⁰ such that

 $\blacktriangleright \succ_{\mathcal{N}}$ is compatible with every conditional importance statement in \mathcal{N}

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

 $\blacktriangleright \succ_{\mathcal{N}}$ is monotonic

A Cl-net of 4 items $\{a, b, c, d\}$: $\{a : d \triangleright bc, a\overline{d} : b \triangleright c, d : c \triangleright b\}$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

A Cl-net of 4 items $\{a, b, c, d\}$: $\{a : d \triangleright bc, a\overline{d} : b \triangleright c, d : c \triangleright b\}$

Induced preference relation $\succ_{\mathcal{N}}$: the smallest preference monotonic relation compatible with all CI-statements.

 we recover the separable, monotonic extension when the CI-net is of the form

 $\begin{array}{l} \varnothing, \varnothing : o_1 \triangleright o_2 \\ \varnothing, \varnothing : o_2 \triangleright o_3; \\ \dots \\ \varnothing, \varnothing : o_{m-1} \triangleright o_m \end{array}$

- Cl-nets can express all strict monotonic preference relations on 2⁰.
- dominance and satisfiability: PSPACE-complete (existence of exponentially long irreducible dominance sequences)
- ▶ in P for precondition-free, singleton-comparing CI-statements (such as $\{a \triangleright c, b \triangleright c, e \triangleright d\}$).

Centralized mechanisms

Cardinal, additive preferences Cardinal, non-additive preferences Ordinal, separable preferences Ordinal, nonseparable preferences

Decentralized mechanisms

Decentralized mechanisms

1. the Descending Demand Protocols

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

- 2. Picking Sequences Protocols
- 3. the Undercut Protocol
- 4. Local Exchange Protocols

The Descending Demand Protocols

- Herreiner and Puppe (2002)
- Basic protocol:
 - ▶ at each step k, each agents gives her best k subset of items
 - stop when we reach a k such that there exists an allocation π such that π(i) is among the top k subsets of agent i.
- ▶ 2 agents (Ann and Bob), 4 items (*a*, *b*, *c*, *d*)

step	Ann	Bob
1	abcd	abcd
2	bcd	abc
3	acd	abd
4	cd	bcd
5	abc	acd
6	abd	bd
7	bc	ac
8	bd	bc

stop and output (bd|ac)

The Descending Demand Protocols

- allows for nonseparable preferences
- resulting allocation maximizes egalitarian social welfare
- resulting allocation may not be envy-free, even when there exists one
- ▶ in (*bd*|*ac*): Bob envies Ann.
- modified DDP:

step	Ann	Bob
1	abcd	abcd
2	bcd	abc
3	acd	abd
4	cd	bcd
5	abc	acd
6	abd	bd
7	bc	ac
8	bd	bc
9	ab	ab

The Descending Demand Protocols

Many nice properties but exponential communication complexity

- with two agents, in the worst case, each agent may have to report half of her preferences
- this worst case is likely to be typical, especially if agents have similar preferences.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Picking Sequences Protocols

strict alternation protocol:

- agent 1 takes an item
- agent 2 takes one of the remaining items

•

- agent n takes one of the remaining items
- agent 1 takes one of the remaining items
- etc.
- example for 2 agents and 8 items: 12121212
- other sequences may be fairer, for instance 12212112
- what about 3 agents and 17 items?
- to each sequence σ : a picking sequence protocol P_{σ} .

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Picking Sequences Protocols

 difficult for the (even nonstrategic) agents to pick the next item if they have nonseparable preferences

- picking sequences 1221
- agent 1: $o_1o_2 \succ o_3o_4 \succ o_1o_3 \succ o_2o_3 \succ o_2o_4 \succ o_1o_4$
- agent 2: $o_1o_2 \succ o_1o_3 \succ o_1o_4 \succ o_2o_3 \succ o_2o_4 \succ o_3o_4$
- what should she pick first?
- the resulting allocation could be $(o_1 o_4 | o_2 o_3)$, Pareto-dominated.
- when all agents have separable preferences:
 - the resulting allocation is Pareto-efficient
 - no guarantee of maxmin fairness or envy-freeness (even when there exists an envy-free efficient allocation)

- communication complexity at most m log m
- more on picking sequences on Thursday.

- Brams, Kilgour and Klamler (2012)
- Two agents (Ann and Bob), 6 items.
- Ann: $e \succ a \succ b \succ f \succ c \succ d$
- Bob: $f \succ e \succ a \succ b \succ c \succ d$
- first phase:
 - agents name their best items
 - if they name different items, each gets the item she names
 - otherwise the item goes into the contested pile CP
 - Ann names and gets *e*, Bob names and gets *f*.
 - Ann and Bob both name a, which goes to the contested pile CP.

Similarly, b, c and d go to the contested pile: $CP = \{a, b, c, d\}$

- Ann: $e \succ a \succ b \succ f \succ c \succ d$
- Bob: $f \succ e \succ a \succ b \succ c \succ d$
- ▶ first phase: Ann gets *e*, Bob gets *f*, $CP = \{a, b, c, d\}$.
- second phase:
 - let $>_i$ be the monotonic separable extension of \succ_i
 - S is a minimal bundle for agent i if
 (a) S ≽_i CP \ S, and
 - (b) for every $T <_i S$, $CP \setminus T \succ_i T$.
 - each agent *i* communicates to the central authority, privately, her set of minimal bundles

Ann:

Ann's preference relation on 2^{CP}:

 $abcd \succ abc \succ abd \succ acd \succ bcd \succ ab \succ ac \succ bc \succ ad \succ bd \succ cd \dots$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- Ann's only minimal bundle: bc
- bc ≻ ad
- ▶ $bd \prec ac, cd \prec ab, b \prec acd, c \prec abd, d \prec abc$

- Ann: $e \succ a \succ b \succ f \succ c \succ d$
- Bob: $f \succ e \succ a \succ b \succ c \succ d$
- ▶ first phase: Ann gets *e*, Bob gets *f*, $CP = \{a, b, c, d\}$.
- second phase:
 - let $>_i$ be the monotonic separable extension of \succ_i
 - S is a minimal bundle for agent i if
 - (a) $S \succeq_i CP \setminus S$, and
 - (b) for every $T <_i S$, $CP \setminus T \succ_i T$.
 - each agent *i* communicates to the central authority, privately, her set of minimal bundles
- Bob:
 - ▶ Bob's preference relation on 2^{CP}:

 $abcd \succ abc \succ abd \succ ab \succ acd \succ ac \succ bcd \succ ad \succ a \succ bc \succ bd \dots$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Bob's minimal bundles: bcd, ad

- Ann: $e \succ a \succ b \succ f \succ c \succ d$
- Bob: $f \succ e \succ a \succ b \succ c \succ d$
- Ann gets e, Bob gets f, $CP = \{a, b, c, d\}$.
- Ann's minimal bundles: $MB_A = \{bc\}$
- Bob's minimal bundles: $MB_B = \{bcd, ad\}$
- Case 1: $MB_A \neq MB_B$.
 - ▶ The central authority proposes (for instance) Bob's most preferred minimal bundles *S* in $MB_B \setminus MB_A$ to Ann.
 - It proposes bcd, to Ann.
 - Ann can choose to take $CP \setminus S$, or to *undercut* S by taking her most preferred bundle among those that are $>_A$ -dominated by S
 - Ann's preference relation on 2^{CP}:

 $abcd \succ abc \succ abd \succ acd \succ bcd \succ ab \succ ac \succ bc \succ ad \succ bd \succ cd \dots$

- Ann can undercut bcd into bc
- since Ann prefers bc to a, Ann takes bc and Bob receives ad
- final allocation [bce|adf].

- Ann: $e \succ a \succ b \succ f \succ c \succ d$
- Bob: $f \succ e \succ a \succ b \succ c \succ d$
- Ann gets e, Bob gets f, $CP = \{a, b, c, d\}$.
- Ann's minimal bundles: $MB_A = \{bc\}$
- Bob's minimal bundles: MB_B = {bcd, ad}
- Case 1: $MB_A \neq MB_B$.
- ▶ Case 2a: $MB_A = MB_B$, and there exists $S \in MB_A$ such that $S \sim_1 CP \setminus S$ (and equivalently, $S \sim_2 CP \setminus S$).
 - Ann receives S and Bob receives $CP \setminus S$ (or vice versa)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- Ann: $e \succ a \succ b \succ f \succ c \succ d$
- Bob: $f \succ e \succ a \succ b \succ c \succ d$
- Ann gets e, Bob gets f, $CP = \{a, b, c, d\}$.
- Ann's minimal bundles: $MB_A = \{bc\}$
- Bob's minimal bundles: MB_B = {bcd, ad}
- Case 1: $MB_A \neq MB_B$.
- Case 2a: $MB_A = MB_B$, and there exists $S \in MB_A$ such that $S \sim_1 CP \setminus S$.
- Case 2b: $MB_A = MB_B$, and no such S exists.
 - ▶ a minimal bundle S is chosen arbitrarily and Ann has to choose between accepting $CP \setminus S$ and undercutting S.
- in cases 1 and 2a, the resulting allocation is envy-free, provided the agent's preferences are separable.

- communication complexity is exponential
- but this is a worst-case bound, and in practice it will often be very small.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Protocols Based on Local Exchanges

- works with a prior allocation (initial endowment or default allocation or randomly selected allocation)
- the agents may contract local exchanges, respecting some rationality criteria
- possibility (or not) of side payments
- depending on several parameters (number of agents and items involved in an exchange, possibility of side payments, possible restrictions on preferences), the process may or may not converge towards a fair allocation, for some given fairness criteria.
- for instance: (Chevaleyre, Endriss, Estivie, Maudet, 2007): if utility functions are supermodular, then a Paretp-efficient envy-free allocation can always be reached.
